1. Introduction

This template allows writing articles in Markdown¹ format. It directly produces well-formatted articles for self-archiving (deposit on HAL for example) or in other formats, for example HTML.

2. R Markdown

Markdown is a very simple language for producing various types of documents: HTML, PDF, and Word among others. Its documentation is available at the RStudio website².

Markdown is extended by Bookdown³, which allows for book writing and more efficient syntax for articles. This document is made with Markdown in RStudio: knitr processes the Markdown code, passes it to Pandoc for transformation into LaTeX, finally LaTeX compiles it into PDF.

2.1 Motivation

Markdown is very easy to learn.

Markdown allows you to integrate your R code for a *reproducible* result.

Markdown allows to produce, without rewriting the text, a document in different formats: HTML, La-TeX or Word for example.

2.2 How to do it

In RStudio, create a new document of type Document R Markdown. The wizard allows you to choose between different formats.

Click on *From template*: from templates installed by packages. The memoiR package templates are displayed: choose *Stylish Article*.

It is better to create an RStudio project to benefit from all the possibilities: File / New Project then use the wizard to create a project from an existing folder.

Write the document in RStudio.

Clicking the **Knit** button in RStudio generates the document in the requested format.

3. Code

The main features of Markdown are summarized here.

3.1 R code

R code is included in code chunks:

head(cars)

```
## speed dist
## 1 4 2
## 2 4 10
## 3 7 4
```

 $^{^{1} \}texttt{https://ericmarcon.github.io/travailleR/} \\ \texttt{chap-rediger.html}$

Table 1. Table created by R

Sepal length	Width	Petal length	Width	Species
5.1	3.5	1.4	0.2	setosa
4.9	3.0	1.4	0.2	setosa
4.7	3.2	1.3	0.2	setosa
4.6	3.1	1.5	0.2	setosa
5.0	3.6	1.4	0.2	setosa
5.4	3.9	1.7	0.4	setosa

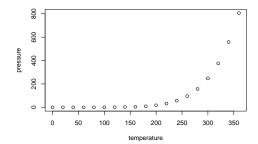

Figure 1. Figure title

4 7 22 ## 5 8 16

3.2 Tables

The horizontal - and vertical separators | allow you to draw a table according to Markdown syntax, but this is not the best method.

Tables can also be produced by R code. The content of the table is in a dataframe. The $\mathtt{kable}()$ function in the knitr package prepares the table for display and passes the result to the $\mathtt{kable_styling}$ function in the kableExtra package for final formatting.

The caption is specified by the caption argument and referencing is possible because the table receives a label whose name is tab: followed by the name of the code snippet (table 1). Always use the booktabs = TRUE argument so that the thickness of the separator lines is optimal in LaTeX. The bootstrap_options = "striped" option provides more readable tables in HTML.

In LaTeX, tables can have the width of the column and possibly span multiple pages, or use the width of the page, like table 2).

This table contains mathematics: the escape = FALSE option is necessary.

Finally, the full_width = FALSE option adjusts the width of the table to its content instead of occupying all the available width. It must be TRUE for correct formatting of two-column tables in LaTeX.

3.3 Figures

plot(pressure)

Figures can be created by the R code (figure 1). With Bookdown, a label is associated with each figure:

Figure 2. A figure from a file

its name is fig:xxx where xxx is the name of the R code snippet. Cross-references are made with the command \@ref(fig:xxx).

A figure can use the full width of the page by adding the following options to the header of the code snippet that generates it: fig.env="figure*" and out.extra="".

Existing figures are integrated into a piece of code by the include_graphics function, see figure 2.

Systematically place these files in the images folder for the automation of GitHub pages.

In the HTML output, figure 2 is located in the margin of the document thanks to the advanced formatting possibilities of the **distill**⁴ package.

3.4 Captions

Figure and table captions can be long, include formatted text, maths, references... The only limit is they cannot contain more than a single paragraph. Such captions must be stored in a separate paragraph starting with (ref:ChunkName) and a space. The text of the caption follows.

In the figure chunk heading, the caption is called in the fig.cap field:

{r ChunkName, fig.cap="(ref:ChunkName)"}

In tables, the caption argument of the kable() function is used the same way.

3.5 Lists

Lists are indicated by *, + and - (three hierarchical levels) or numbers 1., i. and A. (numbered lists). Indentation of lists indicates their level: *, + and - may be replaced by - at all levels, but four spaces are needed to nest a list into another.

- First element of a list
 - sub-list
- Second element
- Continuation of the list

Leave an empty line before and after the list, but not between its items.

Treatment Timber Thinning Fuelwood %AGB lost Control T1 $DBH \ge 50 \text{ cm},$ [12% - 33%]commercial species, $\approx 10 \text{ trees/ha}$ T2 $DBH \ge 50$ cm, $DBH \ge 40 \text{ cm},$ [33% - 56%]commercial species, non-valuable $\approx 10 \text{ trees/ha}$ species, ≈ 30 trees/ha Т3 DBH > 50 cm $DBH \ge 50 \text{ cm},$ 40 cm < DBH < 50[35% - 56%]

non-valuable

species, ≈ 15

trees/ha

Table 2. Intervention table, summary of the disturbance intensity for the 4 plot treatments in Paracou.

3.6 Math

Equations in LaTeX format can be inserted in line, like $A=\pi r^2$ or isolated like

commercial species,

 $\approx 10 \text{ trees/ha}$

$$e^{i\pi} = -1$$
.

They can be numbered, see equation (1), using the equation environment:

$$A = \pi r^2. (1)$$

3.7 Cross-references

Figures and tables have an automatically generated label, identical to the name of the code snippet prefixed with fig: and tab:.

For equations, the label is added manually by the code (\#eq:xxx) before the end of the equation.

Sections can be tagged by ending their title with {#yyy}.

In all cases, the call to the reference is made by the command \c

3.8 Bibliography

Bibliographic references included in the references.bib file can be called by [@CitationKey], in parentheses (Xie, 2016), or without square brackets, in the text, as Xie et al. (2018).

The bibliography is processed by Pandoc when producing Word or HTML documents. The bibliographic style can be specified, by adding the line

in the document header and copying the .csl style file to the project folder. More than a thousand styles are available⁵.

For PDF documents, the bibliography is managed by natbib. The style is declared in the header:

biblio-style: chicago

It can be changed as long as the appropriate .bst file (by default: chicago.bst) is included in the project.

3.9 LaTeX preamble

LaTeX commands can be added in the preamble of the produced LaTeX file, for example to load additional packages. These commands are in the preamble: section of the Markdown file header.

The default commands allow to show the use of the hyphenation command:

\hyphenation%

{bio-di-ver-si-ty sap-lings}

cm, non-valuable

species, ≈ 15

trees/ha

Other commands can be added as needed. Warning:

- Comments are not allowed.
- Complex commands (e.g. \renewenvironment) must be entered on a single line otherwise they will be destroyed by knitr at the first knitting in HTML.

3.10 Forcing line breaks

Hyphenation is handled automatically in LaTeX. If a word is not hyphenated correctly, add its hyphenation in the preamble of the file with the command hyphenation (words are separated by spaces, hyphenation locations are represented by dashes).

If LaTeX can't find a solution for the line break, for example because some code is too long a non-breaking block, add the LaTeX command \break to the line break location. Do not leave a space before the command. The HTML document ignores LaTeX commands.

3.11 Languages

Languages are declared in the document header.

The main language of the document (lang) changes the name of some elements, such as the table of contents. The change of language in the document (one of otherlangs) is managed in LaTeX but not in HTML by inserting on a new line the following command:

\selectlanguage{english}

 $^{^5 \}verb|https://github.com/citation-style-language/styles|$

The current language has an effect only in LaTeX output: a space is added before double punctuation in French, the size of spaces is larger at the beginning of sentences in English, etc. The \selectlanguage command is simply ignored in HTML.

Language codes are used in the header, such as en-US but language names are necessary in \selectlanguage{}. Name matches are listed in table 3 of the polyglossia package documentation⁶.

4. Document types

This template is designed to work with the Stylish Article template in LaTeX and produce documents in PDF, HTML or Word format. Use the list of choices in the *Knit* button to choose the output format.

4.1 PDF Document

The document is formatted for self-archiving of well-formatted articles.

4.2 HTML document

The GitBook template is optimized for on-screen reading. While writing, prefer knitting to HTML format for its speed of execution. A download button is available in the document menu bar: it will work if the document is also knitted in PDF format and if the file name is entered in the download field of the YAML header.

The HMTL Document and all formats from the **rmdformats** packages are other possibilities.

4.3 Word document

Its content can be formatted or copied into a template. The standard text styles are "First Paragraph" and "Body Text".

The advantage of the Word format is to produce a manuscript for journals that do not support LaTeX. The bibliographic style of the journal is most likely available in .csl format, which minimizes manual preparation.

The last line of this template (R code snippet) must be kept to display the title *References* (to be translated into the document language if necessary) in HTML format. The level 1 title *References* must be added manually to Word files.
